SALMON RIVER RAILWAY BRIDGE EXPANSION

CN 2017 Railroad Environmental Conference

October 24, 2017

Overview

- 1. Introduction
- 2. Planning and Design Challenges
- 3. Construction and Restoration
- 4. Post-Construction Monitoring
- 5. Lessons Learned

Overview/Background

- Railway Bridge crosses
 Salmon River approximately
 115 miles east of Toronto
- Salmon River is approximately 70 m wide and over 3 m deep at bridge location
- Supports diverse fish community
- Agency consultation and pre-construction assessments identified two species at risk:
 - Channel Darter (Percina copelandi) Threatened
 - Rainbow mussel (Villosa iris)
 Endangered

Proposed Work

Expand bridge to accommodate third track to facilitate additional passenger train service

Extend two abutments and three piers Install and remove temporary access for construction

Install and remove work area isolation measures Complete mitigation to offset in-water permanent impacts

Planning Challenges

- Located close to Mohawks of the Bay of Quinte First Nation
- Construction requires one year (including inwater winter work) to complete the new bridge
- Habitat for two Species At Risk: Channel Darter and Rainbow Mussel
- Habitat for both species not present near bridge site and difficult to create for compensation
- DFO requires compensation (offsetting) for permit issuance

Bridge Location

Salmon River Bridge and Access

Access Solutions

Typical Habitat Mitigation

"No net loss of productivity of fish habitat"-Fisheries and Oceans Canada guiding principle Identify potential restoration opportunities in immediate vicinity of project – riparian plantings, bank erosion repair Work with local authority (i.e., DFO, conservation authority) to determine appropriate site within same watershed that requires restoration

Mitigation Solution for Salmon River

- Seven options for compensation(now offsetting) were reviewed and assessed based on:
 - constructability
 - feasibility to compensate for impacts to fish habitat
- Reviewed opportunities on and off site
- Habitat for Species at Risk not located near the bridge, difficult to create
- Preferred solution was to enhance habitat for fish species that host Rainbow mussel during larval stage

Fish Habitat Mitigation Options

- 1. Create habitat for Rainbow mussel and Channel Darter within the CN ROW.
- 2. Increase area of mussel bed downstream of bridge.
- 3. Mitigate Lamprey barrier at mouth of Salmon River to improve fish passage.
- 4. Habitat enhancement for Rainbow mussel host fish species.
- 5. Walleye habitat enhancement downstream of Milltown dam.
- 6. Passage for jumping fish at downstream (Milltown) dam.
- 7. Walleye spawning habitat enhancement downstream of DFO Lamprey Barrier near mouth of Salmon River.

Preferred Mitigation Option – #4: Create Habitat for Rainbow Mussel Host Species

- Rainbow mussel require fish species to host larval stage:
 - Smallmouth Bass
 - Rock Bass
 - Yellow Perch
- Create areas of clean gravel with boulders for bass spawning
- Increase in-water cover with large woody debris
- Enhance flooded vegetation areas to provide higher quality spawning and nursery habitat.
- Maintain offsetting measures within CN ROW and on participating landowner property

Habitat Mitigation Plan

Area temporarily disturbed by construction access: 286 m²

Area permanently lost due to bridge expansion: 265 m²

Proposed habitat mitigation components: Large Woody Debris: 20 m² Gravel Habitat: 547 m² Flooded Vegetation: 300 m²

Total Habitat impacted: 551 m²

Total Habitat Created: 867 m²

Construction Access

Construction Access

Construction Access

Habitat Mitigation Installation

Habitat Mitigation Installation

Post Construction Monitoring

DFO authorization required a 5-year postconstruction monitoring program from 2012 to 2017.

> Compensation measures have remained in place and are functioning as designed

Centrarchid nests have been found in gravel habitats when submerged during spring

Juvenile and young-of-the-year Centrarchid captured during fish community surveys

Fish species diversity has remained stable through monitoring program

Monitoring Results – Year 1

Monitoring Results Spawning Habitat

Monitoring Results Fish

Smallmouth Bass

American Eel

Monitoring Results Final

- Mitigation measures on east side of bridge have resulted in:
 - Addition of spawning habitat upstream and under bridge where suitable habitat did not exist prior to construction
 - Improved nursery habitat quality provided with diversified submergent aquatic vegetation upstream of bridge and spawning habitat

Monitoring Results Final

- Mitigation measures on west side of bridge have resulted in:
 - Improved in-water cover provided by addition of large woody debris in form of root wads
 - Improved bank stability through vegetation plantings and root wad installation

Lessons Learned

✓ Designing access and work area isolation measures to 10-year storm event ensured that high water events did not cause delays to construction (difficult to design but no delays)

Site specific Environmental protection measures allowed DFO to approve continuing to work throughout sensitive time periods for species at risk

Habitat compensation /offsetting developed and functional to improve habitat for mussel host species
